TOPICAL ANTIGLAUCOMA COMPOSITIONS COMPRISING CARBONIC ANHYDRASE  
INHIBITORS AND BETA-BLOCKERS

This application is a continuation-in-part of U.S. Patent Application Serial No. 07/837,869, filed February 21, 1992.

Background of the Invention

5 The present invention relates to the field of ophthalmology. In particular, the invention relates to the treatment of glaucoma and associated elevations of intraocular pressure and to the treatment of ocular hypertension associated with other diseases or conditions.

10 Although the underlying causes of glaucoma are not understood, its symptoms often include elevated intraocular pressure, which may be caused either by over-production or inadequate outflow of aqueous humor. If left untreated, or if inadequately treated, glaucoma can lead to blindness or significant loss of vision. There is therefore a continuing need for therapies which control the elevated intraocular pressure associated with glaucoma.

15 There are currently a number of drugs utilized in the treatment of glaucoma, including: miotics (e.g., pilocarpine, carbachol and acetylcholinesterase inhibitors); sympathomimetics (e.g., epinephrine, dipivalylepinephrine and para-amino clonidine); beta-blockers (e.g., betaxolol, levobunolol and timolol); and carbonic anhydrase inhibitors (e.g., acetazolamide, methazolamide and ethoxzolamide). Miotics and  
20 sympathomimetics are believed to lower intraocular pressure ("IOP") by increasing the outflow of aqueous humor, while beta-blockers and carbonic anhydrase inhibitors are believed to lower IOP by decreasing the formation of aqueous humor. All four types of drugs have potentially serious side effects. Miotics such as pilocarpine can cause blurring of vision and other visual side effects, which may lead either to decreased  
25 patient compliance or to termination of therapy. Carbonic anhydrase inhibitors can also cause serious side effects which affect patient compliance and/or necessitate the withdrawal of treatment. Moreover, at least one beta-blocker, timolol, has

C<sub>1-6</sub> alkyl or in which said carbon is substituted optionally with C<sub>1-6</sub> alkyl, C<sub>1-6</sub> alkoxy or OH; and when R<sub>3</sub> is in the 5 position and is H, Cl, Br, or C<sub>1-3</sub> alkyl then neither R<sub>1</sub> nor R<sub>2</sub> can be H or C<sub>1-4</sub> alkyl; and when G is C(=O) and in the 5- position and R<sub>3</sub> is H, then R<sub>1</sub> and R<sub>2</sub> cannot both be CH<sub>3</sub>;

R<sub>7</sub> is: C<sub>1-6</sub> alkyl; C<sub>1-6</sub> alkyl substituted optionally with OH, NR<sub>5</sub>R<sub>6</sub>, halogen, C<sub>1-4</sub> alkoxy

R<sub>9</sub> is: C<sub>1-4</sub> alkyl; C<sub>1-4</sub> alkoxy; amino, C<sub>1-3</sub> alkylamino, or di-C<sub>1-3</sub> alkylamino;

R<sub>10</sub> is: a monocyclic ring system of 5 or 6 atoms composed of C, N, O, and/or S, such  
30 as furan, thiophene, pyrrole, pyrazole, imidazole, triazole, tetrazole, oxazole, isoxazole, isothiazole, thiazole, thiadiazole, pyridine, pyrimidine, pyridazine, and pyrazine; and

G is: C(=O) or SO<sub>2</sub>.

In the above definitions, the total number of carbon atoms in a substituent group is indicated by the  $C_{i,j}$  prefix where i and j are numbers from 1 to 8 for example. This  $C_{i,j}$  definition includes both the straight and branched chain isomers. For example,  $C_{1-4}$  alkyl would designate methyl through the butyl isomers; and  $C_{1-4}$  alkoxy would designate methoxy through the butoxy isomers.

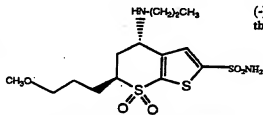

The term "halogen," either alone or in compound words such as "haloalkyl," means fluorine, chlorine, bromine or iodine. Further, when used in compound words such as "haloalkyl," said alkyl may be partially or fully substituted with halogen atoms, which may be the same or different.

Structure (III) includes isomers, wherein  $R_3$  and  $GNR_1R_2$  are attached to the 4 and 5 position respectively or  $R_3$  is attached to the 5 position and  $GNR_1R_2$  is attached to the 4 position. Many of the novel compounds of Structure (III) possess one or more chiral centers and this invention includes all enantiomers, diastereomers and mixtures thereof.

Especially preferred CAIs of the present invention are those listed in Table 1, below.

In general, an amount of a beta-blocker less than or equal to about 2.0% by weight (wt%) and amount of a CAI less than or equal to about 5 wt% are used. It is preferred that an amount of beta-blocker between about 0.01 and about 1.0 wt% is used and it is especially preferred to use an amount between about 0.05 to about 0.5 wt%. An amount of a CAI between about 0.25 and about 3 wt% is preferred and an amount between about 0.5 and about 2 wt% is especially preferred. The ratio by weight of beta-blocker to CAI is generally between about 4:1 to about 1:300, preferably between about 1:1 to about 1:40.

The high molecular weight, anionic mucomimetic polymers useful in the present invention have a molecular weight between about 50,000 and 6 million daltons. The polymers are characterized as having carboxylic acid functional groups and preferably contain between 2 and 7 carbon atoms per functional group. The gels which form during preparation of the ophthalmic polymer dispersion have a viscosity between about 1,000 to about 300,000 centipoise (cps). Suitable polymers are carboxy vinyl polymers, preferably those called Carbomers, e.g., Carbopol® (B.F. Goodrich Co., Cleveland, Ohio). Specifically preferred are Carbopol® 934 and 940. Such polymers will typically be employed in an amount between about 0.05 and about 8.0 wt%, depending on the desired viscosity of the composition. Pourable liquid compositions generally comprise an amount of the polymer between about 0.05 and about 2.0 wt%.

The DCS component of the present compositions is added to provide an additional means of controlling release, as well as to prevent the stinging which often occurs with the topical administration of certain drugs, such as betaxolol. As used herein, the term "finely-divided drug carrier substrate" (or "DCS") means finely-divided solids, colloidal particles, or soluble polymers and/or polyelectrolytes which are capable of selective adsorption or binding with drug molecules. Examples of DCS include, but are not limited to: finely divided silica, such as fumed silica, silicates and bentonites; ion exchange resins, which can be anionic, cationic or non-ionic in nature; and soluble polymers, such as, alginic acid, pectin, soluble carrageenans, Carbopol®, and polystyrene sulfonic acid. Preferred DCS are the ion exchange resins. Some resins which are used in chromatography make ideal DCS for binding drugs in the compositions of the present invention. The DCS component is present in the compositions of the present invention at a concentration between about 0.05 and about 10.0% by weight.

The size of the DCS can be important, both with respect to mode of action and comfort. The average particle size of the typical commercially available form of the DCS material of choice, an ion exchange resin, is about 40 to about 150 microns. Such particles are most conveniently reduced to a particle size range of about 1.0 to

about 25.0 microns, preferably between about 1.0 and 10.0 microns, by ball milling, according to known techniques. In the alternative, small particles may be synthesized in the optimal size range of 3-7 microns. Although this procedure can be more expensive, it is superior in providing a more uniform and narrow distribution of sizes in the preferred range.

These anionic mucomimetic polymers and DCS are discussed in greater detail in U.S. 4,911,920 issued 27 March 1990 and EP 507 224 (published 7 October 1992). The entire contents of the patent and patent application are hereby incorporated by reference herein.

In addition to the above-described principal ingredients, the anti-glaucoma compositions of the present invention may further comprise various formulatroy ingredients, such as antimicrobial preservatives and tonicity agents. Examples of suitable antimicrobial preservatives include: benzalkonium chloride, thimerosal, chlorobutanol, methyl paraben, propyl paraben, phenylethyl alcohol, edetate disodium, sorbic acid, Onamer M® and other agents equally well-known to those skilled in the art. Such preservatives, if utilized, will typically be employed in an amount between about 0.001 to 1.0 wt%. Examples of suitable agents which may be utilized to adjust the tonicity or osmolality of the formulations include: sodium chloride, potassium chloride, mannitol, dextrose, glycerin and propylene glycol. Such agents, if utilized, will typically be employed in an amount between about 0.1 to 10.0 wt%.

As will be appreciated by those skilled in the art, the compositions may be formulated in various dosage forms suitable for topical ophthalmic delivery, including solutions, suspensions, emulsions, gels and erodible solid ocular inserts. The compositions preferably are aqueous, have a pH between 5.0 to 7.8 and an osmolality between 280 to 320 milliOsmoles per kilogram (mOsm/kg).

The following example further illustrates the anti-glaucoma compositions of the present invention.

Preparation:

Compound 3, 12 or 13, and betaxolol or timolol are mixed in 50% of the total water volume component to form an uniform dispersion. Carbopol 934P is slowly added as an aqueous dispersion. The mixture is then homogenized at high speed. The other ingredients are added as aqueous solutions and then water is added to make the final volume. The resultant products, A-F, will be white uniform suspensions.
